(54) Title: BACKLIGHT WITH STRUCTURED SURFACES

(57) Abstract: A backlight includes a lightguide, a light source disposed with respect to the lightguide to introduce light into the lightguide and a turning film. Optical structures are formed in one of an output surface and a back surface of the lightguide. The optical structures are arranged to extract light from the lightguide. A back reflector is disposed adjacent the back surface. The optical structures are formed to include a varying pattern arranged to mask non-uniformities in the output of the lightguide.

BACKLIGHT WITH STRUCTURED SURFACES

BACKGROUND OF THE INVENTION

Field of the Invention

The invention relates generally to a backlight and more particularly to backlights including lightguides formed with optical structures in one or more surfaces of the lightguide.

Description of the Related Technology

Backlit display devices, such as liquid crystal display (LCD) devices, commonly use a wedge-shaped lightguide. The wedge-shaped lightguide couples light from a substantially linear source, such as a cold cathode fluorescent lamp (CCFL), to a substantially planar output. The planar output is then used to illuminate the LCD.

One measure of the performance of the backlit display is its uniformity. A user can easily perceive relatively small differences in brightness of a display from one area of the display to the next. Even relatively small non-uniformities can be very annoying to a user of the display.

Surface diffusers or bulk diffuser sheets, which scatter the light exiting the lightguide, are sometimes used to mask or soften non-uniformities. However, this diffusion also results in light being directed away from a preferred viewing axis. A net result can be a reduction in overall brightness of the display along the preferred viewing axis, which is another performance measure of a display device.

From a subjective standpoint relatively small increases or decreases in overall brightness are not as easily perceived by the user of the display device as are discrete nonuniformities. However, the display device designer is discouraged by even the smallest decreases in

overall brightness including decreases so small they might only be perceived by objective measurement. This is because display brightness and power requirements of the display are closely related. If overall brightness can be increased without increasing the required power, the
5 designer can actually allocate less power to the display device, yet still achieve an acceptable level of brightness. For battery powered portable devices, this translates to longer running times.

SUMMARY OF THE INVENTION

In accordance with the invention, an optical element, such
10 as a lightguide, optical film or lens, is formed with a predetermined, programmed pattern of optical structures. The optical structures may be arranged to selectively correct for non-uniformities in the output of the optical element, or may be arranged to otherwise effect the performance of the display in a predetermined, and designed manner.

15 In a first aspect of the invention, an optically transmissive film having a first surface and a second surface and a first edge and a second edge is formed with a plurality of optical structures formed in the first surface. The plurality of optical structures are arranged on the first surface in a predetermined pattern,
20 and each optical structure has at least one characteristic selected from the group consisting of an amplitude, a period and an aspect ratio. Each characteristic has a first value for a first predetermined location on the film between the first edge and the second edge and the characteristic has a second value, different from the first value, for a
25 second predetermined location on the film, different than the first predetermined location on the film, between the first edge and the second edge.

In another aspect of the invention, the structure in accordance with the invention is part of a thick optical element, such as for example, a lightguide wedge or slab. The structure is achieved on the thick element through injection molding, casting, compression
5 molding, or by bonding a film with the structure to the thick optical element.

BRIEF DESCRIPTION OF THE DRAWINGS

The many advantages and features of the present invention
10 will become apparent to one of ordinary skill in the art from the following detailed description of several preferred embodiments of the invention with reference to the attached drawings wherein like reference numerals refer to like elements throughout and in which:

FIG. 1 is a perspective view of an illumination device
15 adapted in accordance with an embodiment of the invention;

FIG. 2 is a perspective view of an optical film incorporating a programmed pattern of optical structures in accordance with one embodiment of the invention;

FIG. 3 is a perspective view of an optical film
20 incorporating a programmed pattern of optical structures in accordance with another embodiment of the invention;

FIG. 4 is a perspective view of an optical film incorporating a programmed pattern of optical structures in accordance with another embodiment of the invention;

25 FIG. 5 is a perspective view of a lightguide wedge incorporating a programmed pattern of optical structures in accordance with another embodiment of the invention;

FIG. 6 is a perspective view of a lightguide wedge incorporating an in-phase programmed pattern of optical structures in accordance with another embodiment of the invention;

5 FIG. 7 is a cross-section view taken along line 7-7 of FIG. 6;

FIG. 8 is a perspective view of a lightguide wedge incorporating an out-of-phase programmed pattern of optical structures in accordance with another embodiment of the invention;

10 FIG. 9 is perspective view of a linear lens structure incorporating a programmed pattern of optical structures in accordance with another embodiment of the invention;

FIG. 10 is a schematic plan view representation of a circular lens structure incorporating a programmed pattern of optical structures in accordance with another embodiment of the invention;

15 FIG. 11 is a schematic perspective view representation of the circular lens structure shown in FIG. 10;

FIG. 12 is a perspective view of an optical film incorporating a programmed pattern of optical structures in accordance with an alternate preferred embodiment of the invention;

20 FIG. 13 is a perspective view of an optical film incorporating a programmed pattern of optical structures in accordance with an alternate preferred embodiment of the invention;

25 FIG. 14 is a perspective view of an optical film incorporating a programmed pattern of optical structures in accordance with an alternate preferred embodiment of the invention;

FIG. 15 is a perspective view of a lightguide incorporating a first programmed pattern of optical structures in a top surface and a

second programmed pattern of optical structures in a bottom surface in accordance with a preferred embodiment of the invention;

FIG. 16 is a side view illustration of the lightguide shown in FIG. 15;

5 FIG. 17 is an exploded perspective view of a backlight in accordance with a preferred embodiment of the invention;

FIG. 18 is an exploded perspective view of a backlight in accordance with a preferred embodiment of the invention;

10 FIG. 19 is a plot illustrating light output distribution for the backlight illustrated in FIG. 17;

FIG. 20 is a plot illustrating light output distribution for the backlight illustrated in FIG. 18;

FIG. 21 is a side view illustration of a backlight in accordance with the prior art;

15 FIG. 22 is a side view illustration of a backlight in accordance with a preferred embodiment of the invention;

FIGS. 23-28 are side view illustrations of various configurations of backlights in accordance with the preferred embodiments of the invention.

DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENTS

The present invention is described in terms of several preferred embodiments, and particularly, in terms of an optical film or a lightguide suitable for use in a backlighting system typically used in flat panel display devices, such as a laptop computer display or a desktop flat panel display. The invention, however, is not so limited in application and one of ordinary skill in the art will appreciate that it has application to virtually any optical system, for example, to projection screen devices and flat panel televisions. It will be further appreciated that the invention has application to small LCD display devices such as those found in cellular telephones, personal digital assistants (PDAs), pagers, and the like. Therefore, the embodiments described herein should not be taken as limiting of the broad scope of the invention.

Referring to Fig. 1, an illumination system 10 includes a light source 12; a light source reflector 14; a lightguide 16 with an output surface 18, a back surface 20, an input surface 21 and an end surface 22; a reflector 24 adjacent the back surface 20; a first light redirecting element 26; a second light redirecting element 28; and a reflective polarizer 30. The lightguide 16 may be a wedge, a modification thereof or a slab. As is well known, the purpose of the lightguide is to provide for the distribution of light from the light source 12 over an area much larger than the light source 12, and more particularly, substantially over the entire area formed by the output surface 18. The lightguide 16 further preferably accomplishes these tasks in a compact, thin package.

The light source 12 may be a CCFL that inputs light to the

-7-

edge surface 21 of the lightguide 16, and the lamp reflector 14 may be a reflective film that wraps around the light source 12 forming a lamp cavity. The back reflector 24 is located behind the lightguide 16 adjacent to the back surface 20. The back reflector 24 may be an
5 efficient back reflector, e.g., a diffuse reflective film or a specular reflective film.

In the embodiment shown, the edge-coupled light propagates from the input surface 21 toward the end surface 22, confined by total internal reflection (TIR). The light is extracted from the lightguide
10 16 by frustration of the TIR. A ray confined within the lightguide 16 increases its angle of incidence relative to the plane of the top and bottom walls, due to the wedge angle, with each TIR bounce. Thus, the light eventually refracts out of the output surface 18 and at a glancing angle thereto, because it is no longer contained by TIR. Some of the
15 light rays are extracted out of the back surface 20. These light rays are reflected back into and through the lightguide 16 by the back reflector 24. First light redirecting element 26 is arranged as a turning film to redirect these light rays exiting the output surface 18 along a direction substantially parallel to a preferred viewing
20 direction.

With reference still to FIG. 1 and with brief reference also to FIG. 2, the first light redirecting element 26 may be a light transmissive optical film with a first surface 32 and a second surface 34. The first surface 32, in a turning film application, is arranged as
25 an input surface and is formed with prisms 44, which refract and reflect the light exiting the lightguide 16 along the preferred viewing direction. The second surface 34 is therefore an output surface. The

prisms may have a substantially uniform configuration, or may have a non-uniform configuration as described in commonly assigned US patent application "OPTICAL FILM WITH VARIABLE ANGLE PRISMS," Serial No. 09/415,873, filed October 8, 1999, the disclosure of which is hereby
5 expressly incorporated herein by reference.

Referring back to FIG. 1, the second light redirecting element 28 may not be required in every configuration of the illumination system 10. When included in the system 10, the second light redirecting element may be a diffuser, a lenticular spreader or a
10 prism film, for example a brightness enhancing film such as the 3M Brightness Enhancement film product (sold as BEFII or BEFIII) available from Minnesota Mining and Manufacturing Company, St. Paul, Minnesota. The reflective polarizer 30 may be an inorganic, polymeric or cholesteric liquid crystal polarizer film. A suitable film is the
15 Diffuse Reflective Polarizer film product (sold as DRPF) or the Specular Reflective Polarizer film product (sold as DBEF), both of which are available from Minnesota Mining and Manufacturing Company. Furthermore, at least the second light redirecting element 28 and the reflective polarizer 30, and potentially the first light redirecting element 26,
20 may be combined into a single optical element. The commonly assigned US Patent Application entitled "DISPLAY ILLUMINATION DEVICE AND METHOD OF ENHANCING BRIGHTNESS IN A DISPLAY ILLUMINATION DEVICE," Serial No. 09/415,100, filed October 8, 1999, the disclosure of which is hereby
25 expressly incorporated herein by reference, describes several such combined optical structures.

With lightguides used for backlighting, such as the lightguide 16, it is common for there to be non-uniformities in the

light output from the lightguide. These non-uniformities can frequently be concentrated near the input surface 21. To mask non-uniformities, which are generally considered a defect, a diffuser that covers the output surface of the lightguide is typically used. However, a diffuser tends to reduce the overall brightness of the display and may not adequately mask all of the defects.

As described above, in the illumination system 10, the first light redirecting element 26 is arranged as a turning film, and may have a structure as shown in FIG. 2. Referring once again to FIG. 2, the film contains a pattern 42 of optical structures 40 (prisms) that are arranged to have an out-of-phase varying amplitude. For a turning film application, the pattern 42 is formed on a surface that is the light input surface of the film. However, in other applications several of which will be described herein, the pattern 42 may be formed on a top and/or bottom surface of a wedge, slab or film. For the turning film application illustrated in FIG. 1, in addition to the prisms formed on the first surface 32 of the first light redirecting element 26, the second surface 34 may be formed with optical structures.

Continuing with the discussion in connection with FIG. 2, the first light redirecting element 26 has a first edge 36 and a second edge 38. The optical structures 40 extend from the first edge 36 toward the second edge 38 in the pattern 42. Each optical structure 40 may have a number of characteristics, such as amplitude, period and aspect ratio of the peaks 44 and valleys 46. The pattern 42 may also have characteristics, such as for example, a pitch, p , between optical structures 40. The structures 40 in FIG. 2 are shown having amplitude variation. In application of the first light redirecting structure 26,

the grooves may be arranged such that variation in their amplitude is perpendicular to the lightsource 12 (FIG. 1).

With continued reference to FIG. 2, it is observed that within the pattern 42, the optical structures 40 are formed with a larger amount of amplitude variation at the first edge 36, and this amplitude variation decreases in magnitude toward the second edge 38. The larger amount of amplitude variation in the optical structures 40 produces more optical power along the groove axis because of the higher surface slopes. The optical power of this pattern then decreases as a function of the distance from the first edge 36. This arrangement of the optical structures 40 and the pattern 42 is purposeful. As noted, non-uniformities in the output of lightguide 16 may be concentrated near the input surface 21 while there may be less non-uniformity farther from the input surface 21. Thus, the optical structures 40 and the pattern 42 are arranged to provide more diffusion near the first edge 36. In application, the first edge 36 will be disposed substantially adjacent the input surface 21 of the lightguide 16. The pattern 42 has a pitch, p , which may be uniform or variable, and the amplitude of the optical structures 40 may decrease to naught toward the second edge 38. This pattern, as will be discussed in more detail below, may be produced with any tool shape.

It should be appreciated that using ray tracing and other analysis techniques, it is possible to determine particular arrangements for the optical structures 40 and the pattern 42 that best correct particular observed non-uniformities in the output of the lightguide 16. That is, one or more of the characteristics of the optical structures 40 and the pattern 42 may be tailored to correct a particular non-

uniformity. As described above, in connection with first light redirecting element 26, the optical structures 40 and the pattern 42 provided optical power to the output of the lightguide 16 near the input surface 21 in order to mask non-uniformities that may occur near the input surface 21. Less or no optical power is provided away from the input surface 21 as fewer or less intense non-uniformities are typically observed from the lightguide 16 farther from the input surface 21. In this manner, optical power is provided where most needed to mask or soften non-uniformities, while less optical power is provided where there may be less non-uniformity to mask. Moreover, optical power may be added virtually anywhere to the output of the lightguide by adding optical structures and/or varying the characteristics of the optical structures. Furthermore, the addition of optical power need not be uniform. Instead, optical power may be added, as necessary, to discrete regions of the lightguide output if necessary to help mask a defect or create a particular optical effect.

Some lightguides include a pattern of diffuse dots on a back surface of the lightguide. Light incident to one of the dots is diffusely scattered by the diffuse dot, and a portion of this reflected light is caused to exit the light guide. In spite of the diffuse nature of this method of extracting light from the lightguide, the pattern of dots may itself be visible in the lightguide output. Thus, to hide the dot pattern, additional diffusion is typically provided.

With reference to FIG. 3, a film 50 has a surface 52 which is formed to include a plurality of optical structures 54 disposed in a pattern 56. The optical structures 54 are arranged essentially to replace the diffuse dot pattern for providing extraction of light from

the lightguide. While shown in FIG. 3 as ellipses, the optical structures 54 are not collectively limited to any particular shape nor are they limited to any one particular shape within the pattern 56. Therefore, the optical structures 54 may be prisms, lines, dots, squares, ellipses, circles, diamonds or generally any shape or combinations of shapes. Moreover, the optical structures 54 may be made very small in size and may be spaced very closely together within the pattern 56, much more so than the dots within a diffuse dot pattern may be size and spaced. For example, the optical structures may have a size up to the size typical of that used for diffuse dots, but preferably will be smaller than the acuity of the human eye, and may be spaced within about 50-100 μ m of each other. This very small size and close spacing of the optical structures 54 eliminates or reduces the need for diffusion in the output of the lightguide that is ordinarily necessary to hide the pattern of diffuse dots.

Referring to FIG. 4, an optical film 51 has a surface 53 which is formed with a plurality of optical structures 55 disposed in a pattern 57. In this embodiment of the invention, the optical structures 55 are formed as circles or dots. FIG. 5 illustrates a lightguide wedge 59 with a back surface 61 that is formed with optical structures 63 disposed in a pattern 65. The optical structures again are illustrated as circles or dots, but it will be appreciated that the optical structures may take on virtually any configuration.

The invention permits and provides for the changing of the slope of the lightguide at a micro-level. That is, the slope of the lightguide may be locally increased or decreased by the addition of optical structures at the micro-level. When a light ray hits a higher

positive slope, it will be extracted from the lightguide faster than if it hit the nominal wedge angle.

While so far discussed in terms of optical films, the invention has application to the lightguide wedge itself. Referring to FIGS. 6 and 7, a lightguide 60 has an input surface 62, an output surface 64 and a back surface 66. The input surface 62 is arranged to be disposed adjacent a light source (not depicted) to provide a source of light incident to the input surface 62. The light incident to the input surface 62 is extracted out of the output surface 64 as a result of frustrated TIR within the lightguide 60. As discussed above, it is common for there to be non-uniformities in the light output from the lightguide 60, particularly near the input surface 62.

FIG. 7 illustrates the addition of optical power to the back surface 66 of the lightguide 60 and the adjustment in intensity extending away from the input surface 62. As shown in FIG. 6, the back surface 66 is formed with in-phase optical structures 68 arranged to enhance extraction near the input surface 62 and to taper to naught away from the input surface 62. The pattern can also be non-tapering, i.e., constant, over the entire surface, increasing from naught, randomly varying, or distributed in discrete regions. It is also possible for the optical structures to be out-of-phase, such as optical structures 68' formed in a back surface 66' of the lightguide 60' shown in FIG. 8. It will be appreciated that patterns of optical structures may also be formed in the output surface 64 either separately or in conjunction with a pattern formed in the back surface 66 -- such embodiments of the inventions being described more fully below and particularly in connection with FIGS. 15 and 16. Returning to the present discussion, a

purpose of providing the optical structures is to achieve an effect that minimizes non-uniformities of the lightguide output wherever they may occur. For example, the lightguide 60 shown in FIGS. 6 and 8 may have non-uniformities that appear primarily adjacent the input surface 62, which would suggest adding optical structures that have more optical power near the input surface 62.

With particular reference to FIG. 7, the optical structures 68 may be formed on a surface 72 of an optical film 70. The optical film 70 may then be coupled to the wedge structure of the lightguide 60 using ultraviolet (UV) curing, pressure sensitive or any other suitable adhesive. Alternatively, the wedge may be molded in bulk to include the optical structures 68 in the back surface 66.

As will be more generally appreciated from the foregoing discussion, virtually any configuration of optical structures may be formed into an optical film, and the optical film coupled, for example by bonding, to a lightguide or other bulk optical element. For example, glare reduction, anti-wetout, Fresnels, and virtually any other structure that may be formed in a surface of an optical film may be easily replicated into the film and then the film coupled to another optical element.

Films incorporating programmed optical structures may be manufactured using a microreplication process. In such a manufacturing process, a master is made, for example by cutting the pattern into a metal roll, and the master is used to produce films by extrusion, cast-and-cure, embossing and other suitable processes. Alternatively, the films may be manufactured by compression or injection molding, casting or roll forming. A preferred apparatus and method for microreplication

is described in the commonly assigned US patent application entitled
"Optical Film With Defect-Reducing Surface and Method of Making Same,"
serial no. 09/246,970 filed February 9, 1999, (Attorney Docket No.
54176USA9A), the disclosure of which is hereby expressly incorporated
5 herein by reference.

As an example of the above-described feature of the
invention, and with reference to FIG. 9, a linear Fresnel lens or prism
80 has a substantially planar first surface 82 and a second surface 84.
The second surface 84 is formed with lens structures 86 and superimposed
10 on the lens structures 86 are additional optical structures 88. The
optical structures 88 have characteristics, such as amplitude, period,
and aspect ratio, which vary from a first edge 90 of the lens 80 to a
second edge 92 of the lens 80. The lens 80 may be formed in bulk, or as
shown in FIG. 9, the lens structures 86 including the optical structures
15 88 may be formed on a film 94 that is then bonded to a bulk optical
substrate 96. Depending on the application, the first surface 82 may be
arranged as an input surface and the second surface 84 as an output
surface, and vice-versa.

FIGS. 10 and 11 illustrate schematically a circular lens 81
20 that includes a first surface 83 and a second surface 85. The second
surface 85 is formed to include lens structures 87, for example,
circular Fresnel lens structures, and superimposed over the lens
structures 87 are additional optical structures 89. The optical
structures 89 have characteristics, such as amplitude, period, and
25 aspect ratio, which may vary, for example, from an outer circumference
of the lens 81 to the center of the lens 81.

Referring now to FIG. 12, shown graphically is a film 100

containing a varying amplitude pattern 102 of optical structures 108 formed using a "V" shaped cutting tool. The pattern 102 may be formed on a top and/or bottom surface of the film 100. Likewise, the pattern 102 may be formed in a wedge or slab. The film 100 has a first edge 104 and a second edge 106. The optical structures 108 extend from the first edge 104 toward the second edge 106 arranged in the pattern 102. Each optical structure 108 may have a number of characteristics, such as amplitude, period and aspect ratio. The pattern 102 may also have characteristics, such as for example, a pitch, p , defining a spacing between optical structures 108. The optical structures 108 in FIG. 12 are shown having amplitude variation. In application of the film 100, the grooves may be arranged such that the variation in amplitude is perpendicular, parallel or at an angle to a lightsource of the lightguide incorporating the film 100.

With continued reference to FIG. 12, it is observed that within the pattern 102, the optical structures 108 are formed with larger amplitude at the first edge 104 and decrease in amplitude toward the second edge 106. The larger amplitude produces more optical power along the groove axis because of the higher surface slopes. The optical power of this pattern then decreases as a function of the distance from the first edge 104. This arrangement of the optical structures 108 and the pattern 102 is purposeful.

With reference to FIGS. 13 and 14, films 110 and 112, are shown respectively. Each film 110 and 112 has characteristics like film 100, and like reference numerals are used to describe like elements therebetween. As opposed to the pattern created by using a "V" shaped tool, the film 110, FIG. 13, has a pattern 114 of optical structure 116

that is formed using a tool having a curve or arc configuration. The film 112, FIG. 14, has a pattern 118 of optical structures 120 that is formed using a flat nose tool. The patterns 114 and 118 are arranged as described to provide optical power in the surface or surfaces of the films 110 and 112. It will be appreciated that virtually any tool configuration may be used with the particular tool being selected to achieve a desired amount and form of optical power in the surface or surfaces of the film.

In the lightguide 121 illustrated in FIGS. 15 and 16, a first pattern 122 of optical structures 124 is formed in a bottom surface 126 and a second pattern 128 of optical structures 130 is formed in a top surface 132 of the wedge 134. For purposes of illustration only, the optical structures 124 are shown in FIG. 15 to extend only partially across the bottom surface 126, and the optical structures 130 are shown in FIG. 15 to extend only partially across the top surface 132. It will be appreciated that the optical structures 124 and the optical structures 130 will in most cases extend across the entirety of the bottom surface 126 and the top surface 132, respectively. The first pattern 122 may be arranged to facilitate the extraction of light from the wedge 134, while the second pattern 128 may be arranged to mask non-uniformities in the light output from the wedge. It will be appreciated, however, that the patterns implemented in the wedge 134 will depend on the desired light output to be achieved from the wedge 134. Moreover, as described above, the patterns 122 and 128 may be formed first in optical films that are later coupled to the wedge, for example, by bonding. In another construction, surfaces 122 and 128 are formed in the wedge by injection molding or casting.

As is appreciated from the foregoing discussion, and in accordance with the preferred embodiments of the invention, a lightguide may be formed with optical structures, e.g., "V" grooves, in either a first surface, a second surface or both. Whether the first surface or the second surface is an input surface relates to the orientation of the surface with respect to a light source. The optical structures may be uniformly or randomly spaced, and may have various other characteristics. Thus, the invention has application to lightguides and backlight systems for a variety of applications. One example of an application is a backlight system that extracts light by the frustration of total internal reflection where the lightguide is formed with optical structures in either a back surface and/or an output surface thereof. Still another example is a backlight system that has a lightguide that uses a pattern of dots to extract light and includes optical structures formed in either or both of its back and output surfaces. These and other examples are described in more detail below.

Referring to FIG. 17, a backlight 140 is illustrated and includes a light source 142 adjacent an input edge 143 of a wedge lightguide 144. A back reflector 146 is disposed adjacent a back surface 154 of the lightguide 144, and a turning film 148 is disposed adjacent an output surface 150 of the lightguide 144. The back surface 154 is formed with optical structures 152. The optical structures 152 may be grooves formed in the back surface 154, and are shown as such in FIG. 16. The grooves shown in FIG. 17 are "V" grooves and have a prism angle of about 90 degrees, but prism angles ranging from 60 degrees - 120 degrees may be used. Shapes other than "V" grooves may also be used for optical structures 152. Furthermore, each optical structure

may be formed to have a height that varies along its length from a nominal value. This variation may have a wavelength, which may be in the range of about 1 m - 1000 m, preferably be less than about 140 m. Such structures are disclosed and described in the commonly assigned
5 United States Patent Application entitled "Optical Film," Serial No. 09/025,183, filed February 18, 1998 (attorney docket no. 53772USA6A), the disclosure of which is hereby expressly incorporated herein by reference.

The optical structures 152 are shown oriented substantially
10 perpendicular to the light source 142. It will be appreciated that the optical structures 152 may be oriented parallel to the light source 142 or at an angle between 0 degrees - 90 degrees to the light source 142.

The turning film 148 may be any suitable prismatic turning film. For example, the turning film 148 may be formed as described in
15 the aforementioned United States Patent Application entitled "Optical Film With Variable Angle Prisms."

The back surface 154 is formed to include the optical structures 152. This results in some additional light being extracted from the lightguide 144 through the output surface 150 as compared to
20 the light that is extracted from the back surface 154. A portion of the light exiting the back surface 154 will encounter the back reflector 146 and will be reflected back through the lightguide 144 and the output surface 150.

Referring now to FIG. 18, a backlight 140' is illustrated
25 that is similar in construction to the backlight 140, and like reference numerals are used to designate like elements. Primed reference numerals are used to designate elements that are altered from the backlight

construction shown in FIG. 17. The backlight 140' includes a light source 142 adjacent an input edge 143 of a wedge lightguide 144'. A back reflector 146' is disposed adjacent a back surface 154' of the lightguide 144', and a turning film 148 is disposed adjacent an output surface 150' of the lightguide 144'. The output surface 150' is formed with optical structures 152'. The optical structures 152' may be grooves formed in the output surface 150', and are shown as such in FIG. 17. The grooves shown in FIG. 18 are "V" grooves and have a prism angle of about 90 degrees, but prism angles ranging from 60 degrees - 120 degrees may be used. Shapes other than "V" grooves may also be used for optical structures 152'. Furthermore, each optical structure 152' may be formed to have a height that varies along its length from a nominal value. This variation in height may have a wavelength, which may be in the range of about 1 m - 1000 m, but for lightguide applications will preferably be less than about 140 m. Such structures are disclosed and described in the aforementioned United States Patent Application entitled "Optical Film," Serial No. 09/025,183.

The optical structures 152' are shown oriented substantially perpendicular to the light source 142'. It will be appreciated that the optical structures 152' may be oriented parallel to the light source 142' or at an angle between 0 degrees - 90 degrees to the light source 142'.

Forming the output surface 150' to include the optical structures 152' results in additional light being extracted from the lightguide 144 through the back surface 154' as compared to the output surface 150'. Some light is also extracted from the output surface 150'. The portion of the light exiting the back surface 154' will

encounter the back reflector 146' and will be reflected back through the lightguide 144' and the output surface 150. Therefore, with the backlight 140', it may be desirable to directly secure the back reflector 146' to the back surface 154'. This may be accomplished by laminating the back reflector 146' to the back surface 154'. Such an arrangement for the back reflector 146' is disclosed and described in the commonly assigned United States Patent Application, Serial No. 09/414,124, filed October 8, 1999 and entitled "Lightguide Having a Directly Secured Reflector and a Method of Making the Same," the disclosure of which is expressly incorporated herein by reference. Alternatively, the back reflector may be formed on the back surface using a vapor deposition process. In embodiments in which the reflector is directly secured to the back surface of the lightguide, it will be appreciated that the reflector should be both specular and highly efficient with very low absorption.

As described above, variation is added to a characteristic of the optical structures 152 and 152' formed respectively in the back surface or the output surface of the lightguide, e.g., variation in the amplitude of the optical structures, to reduce non-uniformities in the output of the backlight 140 and 140', respectively. It is possible to provide similar variation in the optical structures by other methods, such as by bead blasting the optical structures, however forming the grooves with the described variation in prism height provides a controllable, predictable and hence preferred method of reducing non-uniformities in the output of the backlight.

FIG. 19 illustrates light output in a viewing cone disposed above an output of the backlight 140, i.e., the light exiting the

backlight 140 from an output surface of the turning film 148. What may be determined from the illustrated light output is the on-axis luminance, the maximum luminance, the integrated intensity, the horizontal distribution or horizontal half-angle and the vertical distribution or vertical half-angle. FIG. 20 provides a similar distribution for the backlight 140'. Clearly noticeable is that the output of backlight 140' has a reduced horizontal distribution and a slightly increased vertical distribution. Overall integrated intensity, or the total amount output light from the backlight 140 and 140' is about the same, although on-axis luminance and maximum luminance is substantially increased for the backlight 140' as compared to the backlight 140. Appreciated from the FIGS. 19 and 20, is that the arrangement of optical structures in the lightguides 140 and 140', respectively, will have an effect on the output of the backlight system. In the backlight 140', the lightguide 144' with optical structures 152' formed in its top surface, additional collimation of the light output of the backlight 140' is achieved as compared to the backlight 140. Furthermore, because optical structures 152' may be formed with varying characteristics, as described above, the light output from the backlight 140' may be made uniform without additional optical films or other devices, such as diffusers.

There are additional advantages associated with providing the optical structures 152', including varying characteristics, in the output surface 150' of the lightguide 140'. One such advantage relates to the interface of the output surface 150' with the turning film 148. With the optical structures 152' being formed in the output surface 150', there will be relatively few points of contact between the prisms

of the turning film 148 and the output surface 150'. This may result in a decrease in the optical defect generally referred to as wet-out. As mentioned above, providing variation in the formation of the optical structures 152' helps also to mask defects in the output of the backlight making the light output more uniform. Therefore another advantage of providing the optical structures 152' in the output surface 150' may be the elimination of a diffuser film in the overall backlight system. Because the optical structures 152' provide light collimation, as may be observed from FIG. 20, it is possible, in accordance with the invention, to provide a backlight system that requires fewer sheets of optical film as compared to typical backlight systems.

Illustrated in FIG. 21, are a lightguide 151, a turning film 153, an LCD display 154 and a back reflector 155. Light is extracted from the lightguide 151 from both the top surface 161 and the back surface 157. It is possible that strong Fresnel reflections 156 between the back reflector 155 and the back surface 157 may trap a substantial portion of the light extracted from the back surface 157. This light is ultimately lost leading to inefficiency. To improve this situation, illustrated in FIG. 22, the reflecting surface 158 of the back reflector 155' may be formed with optical structures 159. The optical structures 159 may be facets, grooves or other shaped structures. The optical structures 159 help to reduce the specular component of reflection from back reflector 155' and to direct more light up through the lightguide 151, thus increasing its efficiency. A suitable back reflector including optical structures is the enhanced diffuse reflector (EDR) film product sold by 3M. One of skill in the art will appreciate that the principle taught in FIG. 22 may be applied to virtually any

backlight, including without limitation backlight 140 and backlight systems in accordance with the additional preferred embodiments herein described.

Several adaptations, enhancements and modifications of the backlight systems have been described above. Still others can be appreciated and are within the scope of the invention. It will be appreciated that the particular arrangement of the backlight system will depend on the application for which it is intended. To illustrate the adaptability of the present invention, several examples are shown and described in connection with FIGS. 23-28.

Grooves in the Back Surface of the lightguide

In FIG. 23, a backlight 160 includes a light source 162, a wedge lightguide 164, a back reflector 166, a turning film 168 and an optional additional optical film 170. The lightguide 164 has an output surface 165 and a back surface 172 that is formed with optical structures similar to optical structures 152 shown in connection with the lightguide 144 in FIG. 16. The optical structures may be formed directly into the lightguide 164 by injection molding or casting. Alternatively, the optical structures may be formed in a light transmissive film that is laminated to the back surface 172 of the lightguide 164.

With optical structures formed on the back surface 172 of the lightguide 164 additional light exits the lightguide 164 through the output surface 165 as compared to the back surface 172. The light exiting the back surface 172, however, encounters the back reflector 166, and is reflected back through the lightguide 164. A suitable

reflector including optical structures is a grooved diffuse reflector.

In accordance with additional aspects of the backlight 160, the turning film 168 may be formed to include a diffusive structure in its output surface 176. The optional optical film 170 may be a
5 brightness enhancing film, such as aforementioned BEFIII optical film, the Diffuse Reflective Polarizer film product (sold as DRPF) or the Specular Reflective Polarizer film product (sold as DBEF), all of which are available from Minnesota Mining and Manufacturing Company.

10 Grooves in the Output Surface of the lightguide

In FIG. 24, a backlight 180 includes a light source 182, a wedge lightguide 184, a back reflector 186, a turning film 188 and an optional optical film 190. The lightguide 184 has an output surface 192 that is formed with optical structures similar to optical structures
15 152' shown in connection with the lightguide 144' illustrated in FIG. 17. The lightguide 184 may be formed by injection molding or casting so as to include the optical structures in the output surface 192.

Alternatively, the optical structures may be formed in a light transmissive film that is laminated to the output surface 192 of the
20 lightguide 184. Such an arrangement potentially increases manufacturing flexibility and reduces manufacturing costs by simplifying mold design for the lightguide 184. Instead of having a unique mold for each lightguide, lightguides may be adapted in accordance with the invention by laminating a surface of the lightguide with the optical film formed
25 with the optical structures.

With optical structures formed on the output surface 192 of the lightguide 184 an additional amount of light exits the lightguide

184 from the output surface 192 as compared to the amount of light exiting the lightguide from a back surface 193. The light exiting the back surface 193, however, encounters the back reflector 186, and is reflected back through the lightguide 184. To ensure a high percentage
5 of the light exiting the back surface 193 is reflected back through the lightguide 184, the back reflector 186 is preferably directly secured to the back surface 193. This may be accomplished by laminating a mirror or mirror film to the back surface 193 or by vapor deposition coating the back surface 193. When directly secured to the back surface 193,
10 the back reflector should be specular and highly efficient.

In accordance with additional aspects of the backlight 180, the turning film 188 may be formed to include a diffusive structure in its output surface 196. The optical film 190 may be a brightness enhancing film, such as aforementioned BEFIII optical film, the Diffuse
15 Reflective Polarizer film product (sold as DRPF) or the Specular Reflective Polarizer film product (sold as DBEF), all of which are available from Minnesota Mining and Manufacturing Company.

In FIG. 25, a backlight 220 includes a light source 222, a wedge lightguide 224, a back reflector 226 and a turning film 228. The
20 lightguide 224 has an output surface 230 that is formed with optical structures (not depicted). The optical structures may have a varying pattern, such as described in the aforementioned United States Patent Application entitled "Optical Film," formed using a cutting tool of any suitable shape. The optical structures may be formed directly in the
25 lightguide 224 by injection molding or casting, or alternatively, the optical structures may be formed in a light transmissive film that is laminated to the output surface 230 of the lightguide 224.

With optical structures formed on the output surface 230 of the lightguide 224 an additional amount of light exits the lightguide 224 through the back surface 232 as compared to the amount of light that exits through the output surface 230. This light encounters the back reflector 226, and is reflected back through the lightguide 224. A suitable reflector may be a grooved diffuse reflector. The optical structures may also provide for masking of non-uniformities, and thus eliminate the need for a diffuser in the backlight system.

Also, because the optical structures may also provide collimation of the light exiting the lightguide (see FIG. 20), it is possible, in accordance with the invention, to provide a backlight system that requires fewer sheets of optical film as compared to typical backlight systems. In the embodiment shown in FIG. 25 there is a single, optional, optical film 238, which may be the Diffuse Reflective Polarizer film product (sold as DRPF) or the Specular Reflective Polarizer film product (sold as DBEF) available from Minnesota Mining and Manufacturing Company.

Recycling Backlight Systems

In FIG. 26, a backlight 200 includes a light source 202, a wedge lightguide 204, a back reflector 206, and one or more additional, optional optical films 210 and 212. The lightguide 204 has a back surface 214 that is formed with optical structures similar to optical structures 152 shown in connection with the lightguide 144 in FIG. 17. The optical structures may be formed directly in the lightguide 204 by injection molding or casting. Alternatively, the optical structures may be formed in a light transmissive film that is laminated to the back

surface 214 of the lightguide 204.

The optical structures formed on the back surface 214 of the lightguide 204 facilitate the extraction of light from the lightguide 204. The optical structures may therefore allow for the elimination of the diffuse dot pattern typically used to extract light from the lightguide. Some light exits the back surface 214, and this light encounters the back reflector 206, and is reflected back through the lightguide 204. A suitable back reflector is the enhanced diffuse reflector (EDR) film product sold by 3M.

Elimination of the dot pattern for extraction of light from the lightguide 204 may reduce the need to add diffusion to mask the appearance of the dot pattern in the output of the backlight 200. The optional optical films 210 and 212 may be brightness enhancing films, such as the aforementioned BEFIII optical film product arranged in a crossed arrangement; Diffuse Reflective Polarizer film product (sold as DRPF) the Specular Reflective Polarizer film product (sold as DBEF) and/or various combinations thereof and all of which are available from Minnesota Mining and Manufacturing Company.

In FIG. 27, a backlight 240 includes a light source 242, a wedge lightguide 244, a back reflector 246, a diffuser 248 and first and second optional additional optical films 250 and 252. The back reflector 246 is preferably secured to a back surface 254 of the lightguide 214 using a dot patterned adhesive, such as described in the aforementioned United States Patent Application entitled "Lightguide Having a Directly Secured Reflector." The adhesive is therefore arranged in a dot pattern typical of an extraction dot pattern.

The lightguide 244 has an output surface 255 that is formed

with optical structures (not depicted). The optical structures may have a varying pattern as described above. The optical structures may be formed directly in the lightguide 244 by injection molding or casting, or alternatively, the optical structures may be formed in a light transmissive film that is laminated to the output surface 255 of the lightguide 244.

The optical structures including the varying pattern, as described, may eliminate the need for a diffuser, such as the diffuser 248, to mask the dot pattern, as well as other non-uniformities in the output of the backlight 240. As such, the diffuser 248 is optional. When used, the optional optical films 250 and 252 may be brightness enhancing films, such as the aforementioned BEFIII optical film product, arranged in a crossed arrangement, the Diffuse Reflective Polarizer film product (sold as DRPF) or the Specular Reflective Polarizer film product (sold as DBEF), all of which are available from Minnesota Mining and Manufacturing Company.

Pseudo-Wedge Backlight System

Referring now to FIG. 28, a backlight 260 includes a light source 262 and a pseudo-wedge lightguide 264. The pseudo-wedge lightguide 264 includes a first surface 266 and a second surface 268. The first surface may be formed with optical structures 270, such as optical structures 152 described in connection with FIG. 17. The second surface is formed with faceted groove structures 272 that are arranged to be parallel to the light source 262. The faceted groove structures 272 facilitate extraction of light from the lightguide by enhancing the frustration of total internal reflection. Not shown, the backlight 260

will also include a back reflector disposed adjacent the second surface 268.

5 The faceted groove structures 272 may have variable angle features. Each individual facet has a facet angle. When the faceted groove structures 272 include a variable angle feature, the individual facet angles vary from facet to facet. This arrangement of the faceted groove structures 272 may reduce the appearance of nonuniformities in an output of the backlight 260.

10 While the lightguide 264 is shown as a slab structure, the lightguide 264 may be wedge. Furthermore, the faceted groove structures 272 may be formed directly in the lightguide 264, for example by molding or casting, or the faceted groove structures may be formed in an optical film that is laminated to a slab or wedge lightguide. The faceted groove structures may also vary in density as a function of distance
15 from the light source 262.

Still other modifications and alternative embodiments of the invention will be apparent to those skilled in the art in view of the foregoing description. This description is to be construed as illustrative only, and is for the purpose of teaching those skilled in
20 the art the best mode of carrying out the invention. The details of the structure and method may be varied substantially without departing from the spirit of the invention, and the exclusive use of all modifications which come within the scope of the appended claims is reserved.

CLAIMS

What is claimed is:

1. A backlight comprising:
 - 5 a lightguide,
 - a light source disposed with respect to the lightguide to introduce light into the lightguide;
 - optical structures formed in one of an output surface and a back surface of the lightguide, the optical structures arranged to extract
 - 10 light from the lightguide;
 - a turning film disposed adjacent to the output surface;
 - a back reflector disposed adjacent the back surface; and
 - wherein the optical structures include a varying characteristic arranged to mask non-uniformities in the output of the lightguide.
- 15 2. The backlight of claim 1, wherein the optical structures comprise grooves.
3. The backlight of claim 2, wherein the grooves are arranged
- 20 substantially parallel to the light source.
4. The backlight of claim 2, wherein the grooves are arranged substantially perpendicular to the light source.
- 25 5. The backlight of claim 2, wherein the grooves are arranged at an angle between about 0 degrees to about 90 degrees to the light source.

6. The backlight of claim 2, wherein the grooves have a shape selected from the group of shapes consisting of "V" grooves, flat grooves and arcs.
- 5 7. The backlight of claim 1, wherein the back reflector is directly secured to the back surface.
8. The backlight of claim 1, wherein the back reflector is adhesively bonded to the back surface.
- 10 9. The backlight of claim 1, wherein the back reflector is secured to the back surface by a dot adhesive pattern.
- 15 10. The backlight of claim 1, wherein the back reflector is formed to include optical structures, the optical structures arranged to enhance the reflection of light back through the lightguide.
11. The backlight of claim 1, wherein the lightguide is one of a wedge lightguide, a slab lightguide and a pseudo-wedge lightguide.
- 20 12. The backlight of claim 1, wherein the optical structures are formed in an optical film, and the optical film is laminated to the lightguide.
- 25 13. The backlight of claim 1, wherein the lightguide is formed with optical structures in each of the output surface and the back surface.

14. The backlight of claim 1, wherein the varying characteristic varies as a function of a position on the one of the output surface and the back surface.
- 5 15. The backlight of claim 1, wherein the varying characteristic linearly decreases in magnitude from a first edge of the lightguide to a second edge of the lightguide.
16. An optical film comprising:
- 10 a light transmissive film having a first surface and a second surface; and
- optical structures formed in the first surface, the optical structures including a varying characteristic arranged to mask non-uniformities in an output of the optical film, the varying
- 15 characteristic varying as a function of a position of the varying characteristic on the first surface.
17. The optical film of claim 16, wherein the optical structures comprise grooves.
- 20 18. The optical film of claim 16, wherein the grooves are arranged to be substantially parallel to an edge of the optical film.
19. The optical film of claim 16, wherein the grooves are arranged at
- 25 an angle between about 0 degrees to about 90 degrees to an edge of the optical film.

20. The optical film of claim 16, wherein the second surface of the film is adapted to be secured to one of a back surface and an output surface of a optical film.
- 5 21. The optical film of claim 16, wherein the grooves have a shape selected from the group of shapes consisting of " V" grooves, flat grooves and arcs.
- 10 22. The optical film of claim 16, wherein the varying characteristic linear decreases in magnitude from a first edge of the optical film to a second edge of the optical film.
23. A lens comprising:
a first surface and a second surface, and
15 optical structures formed in one of the first surface and the second surface, the optical structures including a varying characteristic arranged to mask non-uniformities in an output of the lens, the characteristic varying as function of a position of the optical structure on said surface.
- 20 24. The lens of claim 23, the lens having a Fresnel lens structures, and the optical structures being formed in the Fresnel lens structures.
- 25 25. The lens of claim 23, wherein the lens comprises one of a linear lens structure and a circular lens structure.

26. A lightguide comprising:
an input surface, a back surface and an output surface; and
optical structures formed in one of the input surface, the back
surface and the output surface, the optical structures including a
5 varying characteristic arranged to mask non-uniformities in an output of
the lightguide, the characteristic varying as function of a position of
the optical structure on said surface.
27. The lightguide of claim 26, wherein the optical structures are
10 formed in a film and wherein the film is secured to said surface.
28. The lightguide of claim 27, wherein the film is secured to said
surface by bonding.
- 15 29. The lightguide of claim 26, wherein the optical structures
comprise one of "V" grooves, flat grooves and arcs.
30. The lightguide of claim 26, wherein the optical structures
comprise grooves arranged perpendicular to the input edge.
20
31. The lightguide of claim 26, wherein the optical structures
comprise grooves arranged at an angle between 0 degrees to 90 degrees to
the input surface.
- 25 32. The lightguide of claims 26, wherein the optical structures
comprise discrete optical structures dispersed in a pattern.

33. The lightguide of claim 26, wherein the optical structures are formed in each of the back surface and the output surface.

34. The lightguide of claim 26, wherein the back surface is formed
5 with facets and the optical structures are formed in the output surface.

35. The lightguide of claim 26, wherein the varying characteristic varies as a function of a position of the varying characteristic on said surface.

(54) Title: **BACKLIGHT WITH STRUCTURED SUFACES**

(57) Abstract: A backlight includes a lightguide (16), a light source (12) disposed with respect to the lightguide (16) to introduce light into the lightguide (16) and a turning film. Optical structures (40) are formed in one of an output surface (18) and a back surface (20) of the lightguide (16). The optical structures (40) are arranged to extract light from the lightguide (16). A back reflector (24) is disposed adjacent the back surface (20). The optical structures (40) are formed to include a varying pattern arranged to mask non-uniformities in the output of the lightguide (16).

(54) Title: BRIGHTNESS ENHANCEMENT FILM WITH IMPROVED VIEW ANGLE

(57) Abstract: A structural shape on the surface of an optical substrate (110) is such that the brightness of diffuse light departing from the surface of the optical substrate (110) at certain off axis angles is reduced, at the expense of a small reduction in peak brightness measured near the viewing axis. The net result is an overall increase in useful illumination. A cross section of a prism as the structural shape has a curved sidewall or facet. A material with a relatively high index of refraction combined with a prismatic structure having a modified prism geometry improves brightness.

WO 2004/053538 A2

BRIGHTNESS ENHANCEMENT FILM WITH IMPROVED VIEW ANGLE

BACKGROUND OF THE INVENTION

This invention relates to brightness enhancement films and, more specifically to such films having curved facet prism structures and increased prism peak angles and refractive indices.

In backlight computer displays or other systems, optical films are commonly used to direct light. For example, in backlight displays, brightness enhancement films use prismatic structures to direct light along the viewing axis (i.e., an axis normal to the display, or "on axis"). This enhances the brightness of the light viewed by the user of the display and allows the system to use less power to create a desired level of on-axis illumination. Films for turning light can also be used in a wide range of other optical designs, such as for projection displays, traffic signals, and illuminated signs.

Backlight displays and other systems use layers of films stacked and arranged so that the prismatic surfaces thereof are perpendicular to one another and are sandwiched between other optical films known as diffusers. Diffusers have highly irregular surfaces.

The use of current commercial brightness enhancement films causes a sharp cut-off in brightness between about 40 and 50 degrees off-axis. At angles beyond this cut-off there are side-lobes in the angular brightness distribution. These side-lobes can result in a waste of energy because they are outside the desired viewing angle specifications of many liquid crystal display (LCD) devices. The side-lobes are also undesirable in security applications since they allow light to reach unintended viewers.

Thus, there is a continuing and demonstrated need in the prior art for brightness enhancement films which suppress sidelobes in the angular distribution of brightness.

SUMMARY OF THE INVENTION

In a first embodiment, the invention features a structural shape for the surface of an optical substrate such that the brightness of diffuse light departing from the surface of the optical substrate at certain off axis angles is reduced, at the expense of a small reduction in peak brightness measured near the viewing axis. The net result is an overall increase in useful illumination. Such an optical substrate comprises a surface characterized by a cross section of at least one prism having a curved sidewall or facet.

In a second embodiment, the invention features a combination of a high index of refraction prismatic structure with a modified prism geometry. Brightness performance is met or exceeded, for example in an LCD back light display device, when the index of refraction of the prism structure is increased to a value above the index of refraction of materials commonly used in brightness enhancement films, while the peak angle is allowed to increase beyond 90 degrees.

BRIEF DESCRIPTION OF THE DRAWINGS

FIGURE 1 is a cross sectional view of a backlight display device.

FIGURE 2 is a perspective view of an optical substrate comprising a surface characterized by a cross section of a prism having a curved sidewall or facet.

FIGURE 3 is a first cross sectional view of an optical substrate comprising a surface characterized by a cross section of a prism having a curved sidewall or facet.

FIGURE 4 is a second cross sectional view of an optical substrate comprising a surface characterized by a cross section of a prism having a curved sidewall or facet.

FIGURE 5 is a graphical depiction of brightness as a function of horizontal viewing angle for an optical substrate comprising a surface characterized first by a cross section of a right angle prism, second by the curved sidewall or facet in Figure 3 and third by the curved sidewall or facet in Figure 4.

FIGURE 6 is a cross sectional view of a compound angle prism and of the geometric parameters of the curved sidewall or facet of Figures 3 and 4 as described by a segment of a polynomial function.

FIGURE 7 is a perspective view of two optical substrates positioned in a crossed configuration wherein prismatic structures are positioned at an angle with respect to one another (e.g., 90 degrees).

FIGURE 8 is a map of the central luminance of crossed optical substrates as a function of the prism peak angle and the refractive index of the substrate.

FIGURE 9 is a graphical depiction of the far field horizontal luminance of crossed optical substrates as a function of horizontal viewing angle.

FIGURE 10 is a graphical depiction of the far field vertical luminance of crossed optical substrates as a function of vertical viewing angle.

FIGURE 11 is a graphical depiction of the far field horizontal luminance of crossed optical substrates as a function of horizontal viewing angle.

FIGURE 12 is a graphical depiction of the far field vertical luminance of crossed optical substrates as a function of vertical viewing angle.

DETAILED DESCRIPTION OF THE INVENTION

In Figure 1 a cross sectional view of a backlight display device 100 is shown. The backlight display device 100 comprises an optical source 102 for generating light 104. A light guide 106 guides the light 104 therealong by total internal reflection (TIR). The light guide 106 contains disruptive features that cause the light 104 to escape the light guide 106. A reflective substrate 108 positioned along the lower surface of the light guide 106 reflects any light 104 escaping from the lower surface of the light guide 106 back through the light guide 106 and toward an optical substrate 110. At least one optical substrate 110 is receptive of the light 104 from the light guide 106. The optical substrates 110 comprise a three-dimensional surface 112 defined by prismatic structures 116 (Figs. 2, 3 and 4).

The optical substrates 110 may be positioned, one above the other, in a crossed configuration wherein the prismatic structures 116 are positioned at an angle with respect to one another (e.g., 90 degrees) as seen in Figure 7. The prisms 116 have a prescribed peak angle, α , a height, h , a length, l , and a pitch, p and one or both of the prismatic surfaces 112 may be randomized in their peak angle, α , height, h , length, l , and pitch, p . Yet further, one or both sides of the substrates 110 may have the prisms 116. In Figures 2, 3 and 4, in a first embodiment of the invention, the sidewall or facets 132 of the prisms 116 which comprise the surface 112 are curved. The curvature can be described as a segment of a parabola, or more generally as a polynomial surface given by the sag equation:

$$z = \frac{cr^2}{1 + \sqrt{1 - (1+k)c^2r^2}} + dr^2 + er^4 + fr^6 + \text{Higher order terms in } r \quad (1)$$

where z is the perpendicular deviation (or "sag") in microns of the sidewall or facet 132 of the prisms 116 from a straight reference line 128, originating at a first reference point (b) at a base of the prism and terminating at a second reference point (a) near the peak of the prism (see Figure 6) and c^{-1} is the radius of curvature of the facet. Here the coefficients of the polynomial may have the following approximate ranges: $-20 < c < 20$, $-10 < d < 10$, $-10 < e < 10$, $-10 < f < 10$, and $-1 < k$ or less than or equal to zero, wherein r is a radial coordinate or distance from an optical axis in microns. It is noted that c^2r^2 is greater than or equal to zero and less than or equal to 1. Odd order terms in r (e.g., r^1 , r^3 , r^5 , r^7 , etc.) with appropriately chosen coefficients may also be used as in Eq. 1. The higher order terms for the even and odd order terms have appropriately chosen coefficients. Terms other than the first r^2 term may be written as: $\sum_{i=1}^N a_i r^i$.

Linear segments 124, 126 or other approximations to the polynomial described by Eq. 1 may also be used as seen in Figure 6. Linear segments 124, 126 result in a compound angle prism having a first facet 126 at an angle of θ and a second facet 124 at an angle of β . As best understood from Figure 6, the curvature of the curved sidewall or facet 132 of the prisms 116 can be either convex or concave. In Figure 6,

the side facets of the prism are positioned so as to form one or more compound facets 124, 126, respectively subtending an angle of β or θ with the base of the prism.

Sample cross sections of the prisms 116, over a width w , are shown in Figures 2, 3 and 4. Figure 5 is a graphical depiction of brightness as a function of horizontal viewing angle for an optical substrate comprising a surface characterized first 118 by a cross section of a right angled, straight-sided prism, second 122 by the curved sidewall or facet in Figure 3, and third 120 by the curved sidewall or facet in Figure 4. As can be seen in Figure 5, for a right angled, straight-sided prism 118 the brightness shows significant side lobes 128, 130 at a horizontal view angle of approximately ± 50 degrees. These sidelobes are not seen in either of the curved faceted prisms of Figures 3 and 4. However, there is a slight reduction in overall brightness for the curved prisms. As seen by comparing graph 122 with graph 120 in Figure 5, for a refractive index of approximately 1.6 in the optical substrate the steeper the curvature of the side wall the greater the reduction in overall brightness. Also, as seen in Figure 5, as the curvature of the facets increases away from the straight wall of a 90 degree prism, the wider is the central lobe and the lower is the central luminance and the sidelobes.

In a second embodiment, a relatively high index of refraction for the optical substrate 110 in combination with a modified prism geometry yields an enhanced brightness. In particular, Figure 8 displays a map of the central luminance in per cent of crossed optical substrates as a function of the prism peak angle and the refractive index of the substrate, wherein a refractive index of 1.6 and a peak angle of 90 degrees is taken to be 100 per cent. By increasing the peak angle to 100 degrees and increasing the refractive index of the optical substrate generally to greater than about 1.65 and in particular to between approximately 1.7 and 1.8, the luminance is at least 102 per cent.

Figure 9 shows a graphical depiction of the far field horizontal luminance of crossed optical substrates as a function of horizontal viewing angle. In Figure 9, a prior art luminance profile, based upon a refractive index of 1.65 and a peak prism angle of 90 degrees is shown at 150. As can be seen in Figure 9, the prior art shows sidelobes at

152. By increasing the refractive index of the substrates to about 1.75 and the peak prism angle to about 100 degrees, as seen at 154, the central portion of the luminance profile (e.g. +/- 30 degrees) displays a higher peak luminance (about 118) with essentially no sidelobes 156.

Similarly, Figure 10 shows a graphical depiction of the far field vertical luminance of crossed optical substrates as a function of vertical viewing angle. In Figure 10, a prior art luminance profile, based upon a refractive index of 1.65 and a peak prism angle of 90 degrees is shown at 158. As can be seen in Figure 10, the prior art shows sidelobes at 160. By increasing the refractive index of the substrates to about 1.75 and the peak prism angle to about 100 degrees, as seen at 162, the central portion of the luminance profile (e.g. +/- 30 degrees) displays a higher peak luminance (about 118) with suppressed sidelobes 164.

Figure 11 shows a graphical depiction of the far field horizontal luminance of crossed optical substrates as a function of horizontal viewing angle. In Figure 11, a prior art luminance profile, based upon a refractive index of 1.60 and a peak prism angle of 90 degrees is shown at 166. As can be seen in Figure 11, the prior art shows sidelobes at 168. As further seen at 170 in Figure 11, by increasing the peak angle from 90 degrees to about 100 degrees while keeping the refractive index of the substrate at 1.60, the sidelobes 172 are reduced slightly while the central segment of the luminance is only slightly less. Still further, by increasing the refractive index of the substrates to about 1.75 and the peak prism angle to about 100 degrees, as seen at 174, the central portion of the luminance profile (e.g. +/- 30 degrees) displays a slightly higher peak luminance (about 105) with slightly lower sidelobes 176.

Similarly, Figure 12 shows a graphical depiction of the far field vertical luminance of crossed optical substrates as a function of vertical viewing angle. In Figure 12, a prior art luminance profile, based upon a refractive index of 1.60 and a peak prism angle of 90 degrees is shown at 178. As can be seen in Figure 12, the prior art shows sidelobes at 180. As further seen at 182 in Figure 12, by increasing the peak angle from 90 degrees to about 100 degrees while keeping the refractive index of the substrate at 1.60, the sidelobes 184 are reduced while the central segment of the

luminance is only slightly less. Still further, by increasing the refractive index of the substrates to about 1.75 and the peak prism angle to about 100 degrees, as seen at 186, the central portion of the luminance profile (e.g. +/- 30 degrees) displays a higher peak luminance (about 105) with slightly lower sidelobes 188.

Thus, it can be seen from Figures 8 – 12 that by increasing the refractive index of the substrate 110 and/or by increasing the peak angle, α , of the prism structures 116, an improvement is realized in an increase in the on-axis luminance of the optical substrate 110 as well as a reduction in the energy sidelobes of the horizontal and vertical luminance profile.

The optical substrate 110 may be formed from an optically transparent polymer, an ultraviolet (UV) curable organic or inorganic material (or hybrid thereof). In such an optical substrate 110, an index of refraction of greater than about 1.65 is preferred.

Aside from the use of the optical substrates 110 described above in backlight displays for brightness enhancement, the substrates can be used in a wide variety of other applications as well. Embodiments of the substrates 110 can be used in Fresnel lenses, hybrid glass/plastic lenses, optical disks, diffuser films, holographic substrates or in combination with conventional lenses, prisms or mirrors. Such embodiments could be formed by modulating concentric circles or ellipses having fixed characteristics. The optical substrates can also be used in single or multi-order reflective, transmissive or partially transmissive, devices, whether light absorbing or non light absorbing; prisms, holographic optical elements, or diffraction gratings. The substrates can be used in other applications such as projection displays, illuminated signs, and traffic signals. Another property of the invention is that the curved (or compound angle) facets increase the blurring of the light guide features. This is an advantage since it enhances the visual appearance of the display.

Any references to first, second, etc., or front and back, right and left, top and bottom, upper and lower, and horizontal and vertical or any other phrase relating one variable or quantity to another are, unless noted otherwise, intended for the convenience of the description of the invention, and are not intended to limit the present invention or

its components to any one positional or spatial orientation. All dimensions of the components in the attached Figures can vary with a potential design and the intended use of an embodiment without departing from the scope of the invention.

While the invention has been described with reference to several embodiments thereof, it will be understood by those skilled in the art that various changes may be made and equivalents may be substituted for elements thereof without departing from the scope of the invention. In addition, many modifications may be made to adapt a particular situation or material to the teachings of the invention without departing from the essential scope thereof. Therefore, it is intended that the invention not be limited to the particular embodiments disclosed as the best mode contemplated for carrying out this invention, but that the invention will include all embodiments falling within the scope of the appended claims.

CLAIMS

1. An optical substrate (110) comprising:

a surface (112) comprising a prism structure (116) characterized by a cross section having a curved facet described by the equation

$$z = \frac{cr^2}{1 + \sqrt{1 - (1+k)c^2r^2}} + dr^2 + er^4 + fr^6,$$

wherein z is the perpendicular deviation of the surface (112) of the facet of the prism (116) from a straight line originating at a first reference point and terminating at a second reference point and the coefficients of the polynomial lie within the following approximate ranges: $-20 < c < 20$; $-10 < d < 10$; $-10 < e < 10$; $-10 < f < 10$ and $-1 < k$ is less than or equal to zero and where r is a radial coordinate or distance from an optical axis.

2. The optical substrate as set forth in Claim 1 wherein the prism structure (116) comprises a plurality of prisms having a prescribed peak angle, α , a height, h , a length, l , and a pitch, p .

3. The optical substrate as set forth in Claim 2 wherein the plurality of prisms (116) include at least a pseudorandom peak angle, α , height, h , length, l , and pitch, p .

4. The optical substrate as set forth in Claim 1 wherein a peak angle of the prism (116) is greater than 90 degrees and the refractive index of the substrate is between approximately 1.65 and 1.8.

5. The optical substrate as set forth in Claim 4 wherein the peak angle is 100 degrees.

6. An optical substrate (110) comprising:

a surface comprising a prism structure (116) characterized by a peak angle of greater than 90 degrees and a refractive index of between approximately 1.65 and 1.8.

7. The optical substrate (110) as set forth in Claim 6 wherein the peak angle is 100 degrees.

8. A backlight display device (100) comprising:

an optical source (102) for generating light (104);

a light guide (106) for guiding the light (104) therealong including a reflective device (108) positioned along the light guide (106) for reflecting the light (104) out of the light guide (106);

an optical substrate (110) receptive of the light (104) from the reflective device (108), the optical substrate (110) comprising:

a surface comprising a prism structure (116) characterized by a cross section having a curved facet.

9. The backlight display device as set forth in Claim 8 wherein the curved facet is described by a segment of a polynomial function.

10. The backlight display device as set forth in Claim 8 wherein the segment of the polynomial function is described by the equation

$$z = \frac{cr^2}{1 + \sqrt{1 - (1+k)c^2r^2}} + dr^2 + er^4 + fr^6,$$

wherein z is the perpendicular deviation of the surface of the facet of the prism from a straight line originating at a first reference point and terminating at a second reference point and the coefficients of the polynomial lie within the following approximate ranges: $-20 < c < 20$; $-10 < d < 10$; $-10 < e < 10$; $-10 < f < 10$ and $-1 < k$ is less than or equal to zero and where r is a radial coordinate or distance from an optical axis.

11. The backlight display device (100) as set forth in Claim 8 wherein a peak angle of the prism is greater than 90 degrees and the refractive index of the substrate is between approximately 1.65 and 1.8.

12. The backlight display device as set forth in Claim 11 wherein the peak angle is 100 degrees.

13. The backlight display device (100) as set forth in Claim 8 wherein the optical substrate (110) is formed with an optically transparent material with an index of refraction between approximately 1.65 and 1.8.

14. The backlight display device (100) as set forth in Claim 10 wherein the optical substrate (110) is formed with an optically transparent material with an index of refraction of approximately 1.75.

15. An optical substrate (110) comprising:

a surface (112) comprising a prism structure (116) characterized by a cross section having a plurality of facets including a first facet (126) oriented at a first angle with respect to the surface of the prism and a second facet (124) oriented at a second angle with respect to the surface of the prism;

wherein the first and second facets (124, 126) intersect at one side of a centerline of the prism and the first and second angles are different.

16. The optical substrate (110) as set forth in Claim 15 wherein a peak angle of the prism structure is greater than 90 degrees and the refractive index of the substrate is between approximately 1.65 and 1.8.

17. The optical substrate (110) as set forth in Claim 16 wherein the peak angle is 100 degrees.

18. The optical substrate (110) as set forth in Claim 1 wherein the prism structure (116) is an ultraviolet curable organic or inorganic material.

19. The optical substrate (110) as set forth in Claim 6 wherein the prism structure (116) is an ultraviolet curable organic or inorganic material.

20. The backlight display device (100) as set forth in Claim 8 wherein the prism structure is an ultraviolet curable organic or inorganic material.

21. The optical substrate (110) as set forth in Claim 15 wherein the prism structure (116) is an ultraviolet curable organic or inorganic material.

22. The optical substrate (110) as set forth in Claim 1 wherein the prism structure (116) includes a peak angle of greater than approximately 94 degrees and wherein c , d , e , f , and k are approximately equal to zero.

23. The optical substrate (110) as set forth in Claim 1 wherein the equation for z includes higher order terms in r defined by the summation $\sum_{i=1}^N a_i r^i$ where a_i are coefficients and N is an integer.

24. The optical substrate (110) as set forth in Claim 10 wherein the prism structure (116) includes a peak angle of greater than approximately 94 degrees and wherein c , d , e , f , and k are approximately equal to zero.

25. The optical substrate (110) as set forth in Claim 10 wherein the equation for z includes higher order terms in r defined by the summation $\sum_{i=1}^N a_i r^i$ where a_i are coefficients and N is an integer.

26. An optical substrate (110) comprising:

a surface comprising a prism structure (116) characterized by a cross section having a facet described by the equation

$$z = \frac{cr^2}{1 + \sqrt{1 - (1+k)c^2 r^2}},$$

wherein z is the perpendicular deviation of the surface of the facet of the prism from a straight line originating at a first reference point and terminating at a second reference point.

27. The optical substrate (110) as set forth in Claim 26 wherein the equation further comprises a summation of higher order terms

$$+ dr^2 + er^4 + fr^6$$

wherein the coefficients thereof lie within the following approximate ranges: $-20 < c < 20$; $-10 < d < 10$; $-10 < e < 10$; $-10 < f < 10$ and $-1 < k$ is less than or equal to zero and where r is a radial coordinate or distance from an optical axis.

28. An optical substrate (110) comprising:

a surface comprising a prism structure (116) characterized by a cross section having a plurality of facets intersecting at a peak so as to subtend a peak angle of α .

29. The optical substrate (110) as set forth in Claim 28 wherein the plurality of facets form one or more compound facets respectively subtending an angle of β or θ with a base of the prism.

(54) Title: BRIGHTNESS ENHANCEMENT FILM WITH IMPROVED VIEW ANGLE

(57) Abstract: A structural shape on the surface of an optical substrate (110) is such that the brightness of diffuse light departing from the surface of the optical substrate (110) at certain off axis angles is reduced, at the expense of a small reduction in peak brightness measured near the viewing axis. The net result is an overall increase in useful illumination. A cross section of a prism as the structural shape has a curved sidewall or facet. A material with a relatively high index of refraction combined with a prismatic structure having a modified prism geometry improves brightness.

INTERNATIONAL SEARCH REPORT

International Application No.

PCT/US 03/37059

A. CLASSIFICATION OF SUBJECT MATTER

IPC 7 G02B6/00

According to International Patent Classification (IPC) or to both national classification and IPC

B. FIELDS SEARCHED

Minimum documentation searched (classification system followed by classification symbols)

IPC 7 G02B

Documentation searched other than minimum documentation to the extent that such documents are included in the fields searched

Electronic data base consulted during the international search (name of data base and, where practical, search terms used)

EPO-Internal, PAJ, WPI Data

C. DOCUMENTS CONSIDERED TO BE RELEVANT

Category *	Citation of document, with indication, where appropriate, of the relevant passages	Relevant to claim No.
X	US 2002/141060 A1 (JACOB DAVID A ET AL) 3 October 2002 (2002-10-03) paragraph '0048!; figures 4,8,10,11	1, 2, 28, 29

☒ Further documents are listed in the continuation of box C.☒ Patent family members are listed in annex.

* Special categories of cited documents:

A document defining the general state of the art which is not considered to be of particular relevance

E earlier document but published on or after the international filing date

L document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)

O document referring to an oral disclosure, use, exhibition or other means

P document published prior to the international filing date but later than the priority date claimed

T later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention

X document of particular relevance; the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is taken alone

Y document of particular relevance; the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art.

INTERNATIONAL SEARCH REPORT

national application No.
PCT/US 03/37059

Box I Observations where certain claims were found unsearchable (Continuation of item 1 of first sheet)

This International Search Report has not been established in respect of certain claims under Article 17(2)(a) for the following reasons:

1. ☐ Claims Nos.:
because they relate to subject matter not required to be searched by this Authority, namely:
2. ☐ Claims Nos.:
because they relate to parts of the International Application that do not comply with the prescribed requirements to such an extent that no meaningful International Search can be carried out, specifically:
3. ☐ Claims Nos.:
because they are dependent claims and are not drafted in accordance with the second and third sentences of Rule 6.4(a).

Box II Observations where unity of invention is lacking (Continuation of item 2 of first sheet)

This International Searching Authority found multiple inventions in this international application, as follows:

see additional sheet

1. ☐ As all required additional search fees were timely paid by the applicant, this International Search Report covers all searchable claims.
2. ☐ As all searchable claims could be searched without effort justifying an additional fee, this Authority did not invite payment of any additional fee.
3. ☒ As only some of the required additional search fees were timely paid by the applicant, this International Search Report covers only those claims for which fees were paid, specifically claims Nos.:
1-5, 8-14, 18, 20, 22-29
4. ☐ No required additional search fees were timely paid by the applicant. Consequently, this International Search Report is restricted to the invention first mentioned in the claims; it is covered by claims Nos.:

Remark on Protest

☐ The additional search fees were accompanied by the applicant's protest.

☒ No protest accompanied the payment of additional search fees.

FURTHER INFORMATION CONTINUED FROM PCT/ISA/ 210

This International Searching Authority found multiple (groups of) inventions in this international application, as follows:

1. claims: 1-5,18,22,23,26-29

1.1. claims: 1-5,18,22,23,26,27

Optical substrate with a prism structure characterised by having a curved facet described by a polynomial sag equation

1.2. claims: 28,29

Optical substrate with a prism structure having a cross section comprising a plurality of facets intersecting at a peak to subtend a peak angle α

2. claims: 6,7,19

Optical substrate with a prism structure characterised by a peak angle $> 90^\circ$ and having a refractive index between 1.65 and 1.8

3. claims: 8-14,20,24,25

Backlight display device characterised by comprising, among other, an optical substrate with a prism structure having a curved facet

4. claims: 15-17,21

Optical substrate with a prism structure characterised by the prism structure comprising two intersecting facets oriented at different angles
